Development of micro-RNAs as diagnostic and prognostic biomarkers for non-small cell lung cancer. Non-small cell lung cancer (NSCLC) is one of the most common malignancies in the world, with a mortality rate of approximately 80% at 5 years. Cytologic examination of the sputum or the pleural effusion remains the mainstay of diagnosis. In this article, we review the methods for detection of circulating tumor cells and circulating microRNAs (miRNAs) in the blood for the diagnosis and prognosis of NSCLC. We also analyze the current state of the research on the detection of miRNAs in plasma/serum. A computerized search of MEDLINE, PubMed, and ScienceDirect from the earliest available date was carried out for relevant articles on circulating miRNAs in the blood and diagnosis and prognosis of NSCLC. Several lines of evidence suggest that miRNAs are potential biomarkers for cancer diagnosis, including their stability in serum/plasma, their tissue-specificity, and their expression patterns in specific diseases. The expression levels of specific miRNAs (such as miR-200, miR-21, and miR-141) have been associated with the malignant transformation and the progression of NSCLC and the development of therapeutic resistance, and thus could be used as potential biomarkers for the diagnosis, prognosis, and monitoring of treatment response of NSCLC. Circulating miRNAs may be used as potential biomarkers for the diagnosis and prognosis of NSCLC. is covered or not. * * @param sTarget the byte string
